Introduction to Semiconductor Physics and Devices - YouTube

A semiconductor material has an electrical conductivity value falling between that of a conductor, such as metallic copper, and an insulator, such as glass. Its resistivity falls as its temperature rises; metals are the opposite. Its conducting properties may be altered in useful ways by introducing impurities ("doping") into the crystal structure. When two differently-doped regions exist in the ...

The basic function of such a device is to switch ON and OFF the flow of electricity as and when required. A semiconductor device can perform the function of a vacuum tube with hundreds of times its volume. A single integrated circuit (IC), such as a microprocessor chip, can do the work of a set of vacuum tubes.

A semiconductor is a substance whose resistivity lies between the conductors and insulators. The property of resistivity is not the only one that decides a material as a semiconductor, but it has few properties as follows. Semiconductors have the resistivity which is less than insulators and more than conductors.

Semiconductor Physics and Devices: Basic Principles, 4th edition Chapter 3 D. A. Neamen Problem Solutions Chapter 3 3.1 If ϕ_0 were to increase, the bandgap energy would decrease and the material would begin to behave less like a semiconductor and more like a metal. If ϕ_0 were to decrease, the bandgap energy would increase and the material would begin to behave more like an insulator. 3.2 wave equation is: $2.2 \times 10^8 \text{ V/m}$ $2 \times 10^8 \text{ t}$ Assume the solution is of the form: $E = E_0 \exp(j k x + t)$ Region ...
